

AP0202AT High-Dynamic Range (HDR) Image Signal Processor (ISP)

AP0202AT Datasheet, Rev. 4

For the latest product datasheet, please visit www.onsemi.com

Features

- Up to 2.0 Mp (1920x1080) ON Semiconductor sensor support
- 30 fps at 1080p, 45 fps at 1.2Mp, 60 fps at 720p (Optimized for operation with HDR sensors)
- Color and gamma correction
- Auto exposure, auto white balance, 50/60 Hz auto flicker detection and avoidance
- Adaptive Local Tone Mapping (ALTM)
- Two-wire serial programming interface (CCIS)
- Parallel output
- Configurable through low-cost SPI Flash and EEPROM devices
- High-level host command interface
- Standalone operation supported
- Up to 7 GPIO
- Fail-safe IO
- Multi-Camera synchronization support

Applications

- Surround, rear and front view cameras
- Blind spot / side mirror replacement cameras
- Automotive viewing/processing fusion cameras

Table 1: Key Performance Parameters

| Parameter | Value | |
|----------------------------|---|-----------------------------|
| Image sensor interfaces | Parallel and HiSPi | |
| Input Data Format | Parallel: 12 bit SDR (linear) or 12 bit HDR companded. HiSPi: 12 bit SDR (linear) or 12/14 bit HDR companded | |
| Output interface | Up to 24-bit parallel ¹ | |
| Output format | RGB888, RGB565, YUV422 8-/10-bit ¹ | |
| Maximum resolution | 1920 x 1080 (2.0 Mp) | |
| Input clock range | 10 - 29 MHz | |
| Output pixel clock maximum | 125 MHz ² | |
| Supply voltage | VDDIO_S | 1.8 or 2.8 V nominal |
| | VDDIO_H | 1.8 or 2.8 or 3.3 V nominal |
| | VDD_REG | 1.8 V nominal |
| | VDD | 1.2 V nominal |
| | VDD_PLL | 1.2 V nominal |
| | VDD_PHY | 2.8 V nominal |
| | VDDIO_OTPM | 2.5 to 3.3 V nominal |
| Operating temp. (Ambient) | -40°C to +105°C | |
| Power consumption | 250 mW | |

Notes: 1. Maximum frame rates depend on output interface and data format configuration used.
2. Maximum pixel clock rates depend on IO voltage.

Ordering Information

Table 2: Available Part Numbers

| Part Number | Product Description | Orderable Product Attribute Description |
|-------------------------|------------------------------|---|
| AP0202AT2L00XPGA0-DR | Co-Processor, 100-ball VFBGA | Drypack |

General Description

ON Semiconductor's AP0202AT Image Signal Processor (ISP) is optimized for use with HDR (High Dynamic Range) sensors. The AP0202AT provides full auto-functions support (AWB and AE) and ALTm (Adaptive Local Tone Mapping) to enhance HDR images and advanced noise reduction which enables excellent low-light performance.

Functional Overview

Figure 1 shows the typical configuration of the AP0202AT in a camera system. On the host side, a two-wire serial or SPI interface is used to configure the operation of the AP0202AT, and image data is transferred using the parallel interface between the AP0202AT and the host. The AP0202AT interface to the sensor supports a parallel interface or HiSPi interface.

Figure 1: AP0202AT Connectivity

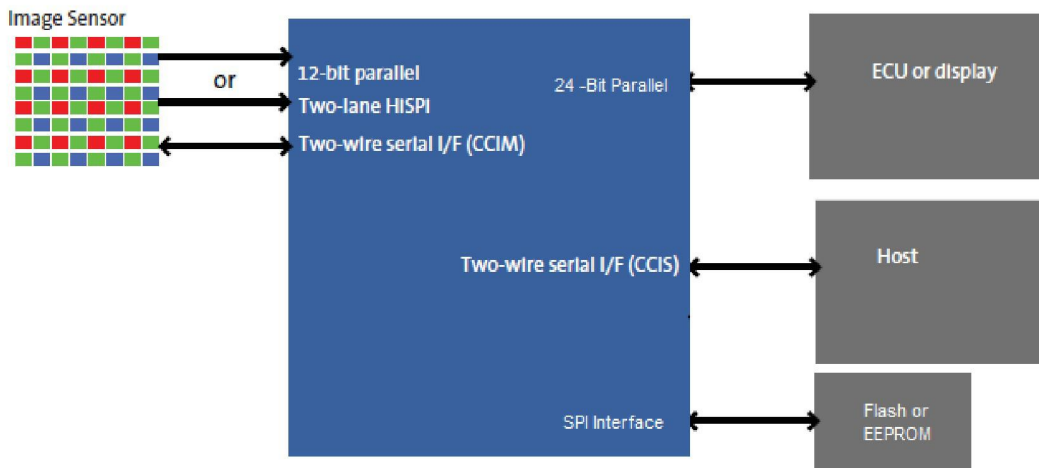

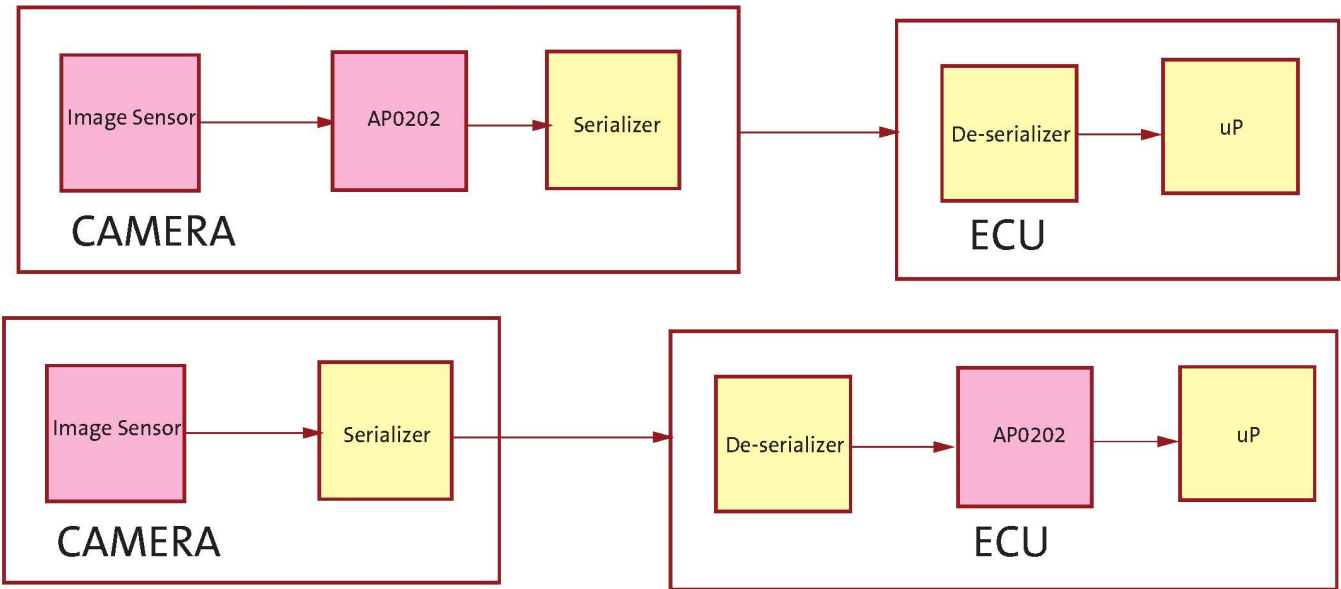

Figure 2: Examples AP0202AT Connectivity

The AP0202AT also supports a Serializer and Deserializer between the sensor and ISP. The AP0202AT supports clock stretching on the slave 2-wire interface.

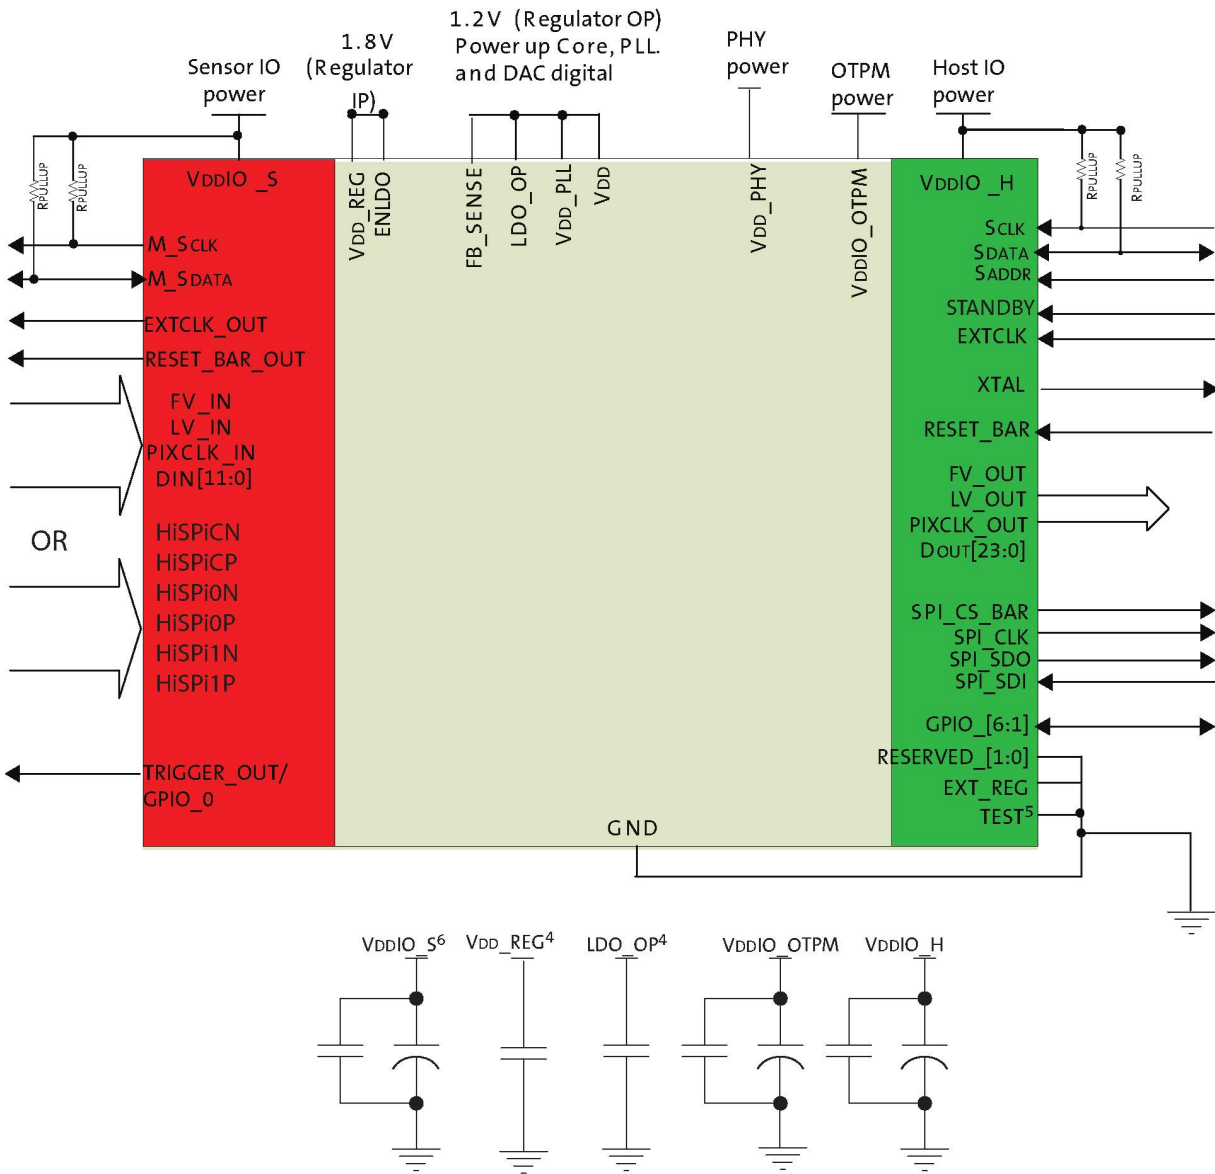

System Interfaces

Figure 3 shows typical AP0202AT device connections.

All power supply rails must be decoupled from ground using capacitors as close as possible to the package.

The AP0202AT signals to the sensor and host interfaces can be at different supply voltage levels to optimize power consumption and maximize flexibility. Table 3 on page 11 provides the signal descriptions for the AP0202AT.

Figure 3: Typical Parallel Configuration - Legacy Mode

Notes: 1. This typical configuration shows only one scenario out of multiple possible variations for this device.

2. ON Semiconductor recommends a 1.5k Ω resistor value for the two-wire serial interface R_{PULL-UP}; however, greater values may be used for slower transmission speed.
3. RESET_BAR has an internal pull-up resistor and can be left floating if not used.
4. The decoupling capacitors for the regulator input and output should have a value of 1.0 μ F. The capacitors should be ceramic and need to have X5R or X7R dielectric.
5. TEST and RESERVED_[1:0] connect to GND for normal operation.
6. ON Semiconductor recommends that 0.1 μ F and 1 μ F decoupling capacitors for each power supply are mounted as close as possible to the pin. Actual values and numbers may vary depending on layout and design consideration.
7. The diagram is showing Legacy mode. If Crossbar is used, the 27 parallel outputs can be assigned to any pin. Refer to crossbar section for more details.

HiSPi and Parallel Connection

When using the HiSPi interface, connect the parallel interface to VDDIO_S.

When using the parallel interface, it is recommended for the HiSPi interface to be connected to ground, and the power supply (VDD_PHY) to be connected to +2.8V. Floating these pins is allowed as well.

Crystal Usage

As an alternative to using an external oscillator, a crystal may be connected between EXTCLK and XTAL. Two small loading capacitors and a feedback resistor should be added, as shown in Figure 4.

For applications above 85°C, ON Semiconductor does not recommend using the crystal option. A crystal oscillator with temperature compensation is recommended for applications that require this.

Figure 4: Using a Crystal Instead of an External Oscillator

R_f represents the feedback resistor, an R_f value of 1M Ω is sufficient for AP0202AT. C₁ and C₂ are decided according to the crystal or resonator CL specification. In the steady state of oscillation, CL is defined as $(C_1 \times C_2) / (C_1 + C_2)$. In fact, the I/O ports, the bond pad, package pin and PCB traces all contribute the parasitic capacitance to C₁ and C₂. Therefore, CL can be rewritten to be $(C_1^* \times C_2^*) / (C_1^* + C_2^*)$, where $C_1^* = (C_1 + C_{IN, STRAY})$ and

$C2^* = (C2 + C_{OUT, STRAY})$. The stray capacitance for the IO ports, bond pad and package pin are known which means the formulas can be rewritten as $C1^* = (C1 + 1.5pF + C_{IN, PCB})$ and $C2^* = (C2 + 1.3pF + C_{OUT, PCB})$.

Pin Descriptions

Table 3: Pin Descriptions

| Name | Type | Description |
|--------------------|----------|---|
| EXTCLK | Input | Master input clock. This can either be a square-wave generated from an oscillator (in which case the XTAL input must be left unconnected) or direct connection to a crystal. |
| XTAL | Output | If EXTCLK is connected to one pin of a crystal, the other pin of the crystal is connected to XTAL pin; otherwise this signal must be left unconnected. |
| RESET_BAR | Input/PU | Master reset signal, active LOW. This signal has an internal pull up. |
| SCLK | Input | Two-wire serial interface clock (host interface). |
| SDATA | I/O | Two-wire serial interface data (host interface). |
| SADDR | Input | Selects device address for the two-wire slave serial interface. When connected to GND the device ID is 0x90. When wired to VDDIO_H, a device ID of 0xBA is selected. |
| FRAME_SYNC | Input | Pass through to TRIGGER_OUT. This signal should be connected to GND if not used. |
| STANDBY | Input | Standby mode control, active HIGH. |
| EXT_REG | Input | Select external regulator if tied high |
| ENDLO | Input | Regulator enable (VDD_REG domain) |
| SPI_SCLK | Output | Clock output for interfacing to an external SPI flash or EEPROM memory. |
| SPI_SDI | Input | Data in from SPI flash or EEPROM memory. When no SPI device is fitted, this signal is used to determine whether the AP0202AT should auto-configure: 0: Do not auto-configure; Two-wire interface will be used to configure the device (host-config mode) 1: Auto-configure. This signal has an internal pull-up resistor. |
| SPI_SDO | Output | Data out to SPI flash or EEPROM memory. |
| SPI_CS_BAR | Output | Chip select out to SPI flash or EEPROM memory. |
| EXT_CLK_OUT | Output | Clock to external sensor. |
| RESET_BAR_OUT | Output | Reset signal to external signal. |
| M_SCLK | Output | Two-wire serial interface clock (Master). |
| M_SDATA | I/O | Two-wire serial interface clock (Master). |
| FV_IN | Input | Sensor frame valid input. |
| LV_IN | Input | Sensor line valid input. |
| PIXCLK_IN | Input | Sensor pixel clock input. |
| DIN[11:0] | Input | Sensor pixel data input DIN[11:0] |
| HiSPiCN | Input | Differential HiSPi clock (negative). |
| HiSPiCP | Input | Differential HiSPi clock (positive). |
| HiSPi0N | Input | Differential HiSPi data, lane 0 (negative). |
| HiSPi0P | Input | Differential HiSPi data, lane 0 (positive). |
| HiSPi1N | Input | Differential HiSPi data, lane 1 (negative). |
| HiSPi1P | Input | Differential HiSPi data, lane 1 (positive). |
| TRIGGER_OUT/GPIO_0 | Output | Trigger signal for external sensor. |
| FV_OUT | Output | Host frame valid output (synchronous to PIXCLK_OUT) |
| META_LINE_VALID | Output | Line valid signal to indicate when Metadata is valid. In addition, there is a variable option to allow META_LINE_VALID to be reflected in LV_OUT |
| LV_OUT | Output | Host line valid output (synchronous to PIXCLK_OUT) |
| PIXCLK_OUT | Output | Host pixel clock output. |
| Dout[23:0] | Output | Host pixel data output (synchronous to H_PIXCLK_OUT). |

Table 3: Pin Descriptions

| Name | Type | Description |
|----------------|--------|---|
| GPIO_[6:1] | I/O | General purpose digital I/O. |
| TEST | Input | Must be tied to GND in normal operation. |
| RESERVED_[1:0] | Input | Must be tied to GND in normal operation. |
| VDDIO_S | Supply | Sensor I/O power supply. |
| VDDIO_H | Supply | Host I/O power supply. |
| VDD_PLL | Supply | PLL supply. |
| VDD | Supply | Core supply. |
| VDDIO_OTPM | Supply | OTPM power supply. |
| VDD_PHY | Supply | PHY IO voltage for HiSPi |
| GND | Supply | Ground |
| VDD_REG | Supply | Input to on-chip 1.8V to 1.2V regulator. |
| LDO_OP | Output | Output from on chip 1.8V to 1.2V regulator. |
| FB_SENSE | Input | On-chip regulator sense signal. |

Table 4: Package Pinout

| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

| J | PIXCLK_OUT | DOUT22 | DOUT19 | DOUT17 | DOUT13 | DOUT10 | DOUT7 | DOUT3 | DOUT0 | LDO_OP |
| K | DOUT23 | VDDIO_H | DOUT20 | DOUT15 | VDD | DOUT11 | DOUT9 | DOUT4 | DOUT1 | GND |

On-Chip Regulator

The AP0202AT has an on-chip regulator, the output from the regulator is 1.2V and should only be used to power up the AP0202AT. It is possible to bypass the regulator and provide power to the relevant pins that need 1.2V. The following table summarizes the key signals when using/bypassing the regulator.

Table 5: Key Signals When Using the Regulator

| Signal Name | Internal Regulator | External Regulator |
|-------------|---------------------------|--------------------|
| VDD_REG | 1.8V | Connect to VDDIO_H |
| ENLDO | Connect to 1.8V (VDD_REG) | GND |
| FB_SENSE | 1.2V (input) | Float |
| LDO_OP | 1.2V (output) | Float |
| EXT_REG | GND | Connect to VDDIO_H |

Power-Up Sequence

Powering up the AP0202AT requires voltages to be applied in a particular order, as seen in Figure 5. The timing requirements are shown in Table 6. The AP0202AT includes a power-on reset feature that initiates a reset upon power up.

Figure 5: Power-Up and Power-Down Sequence

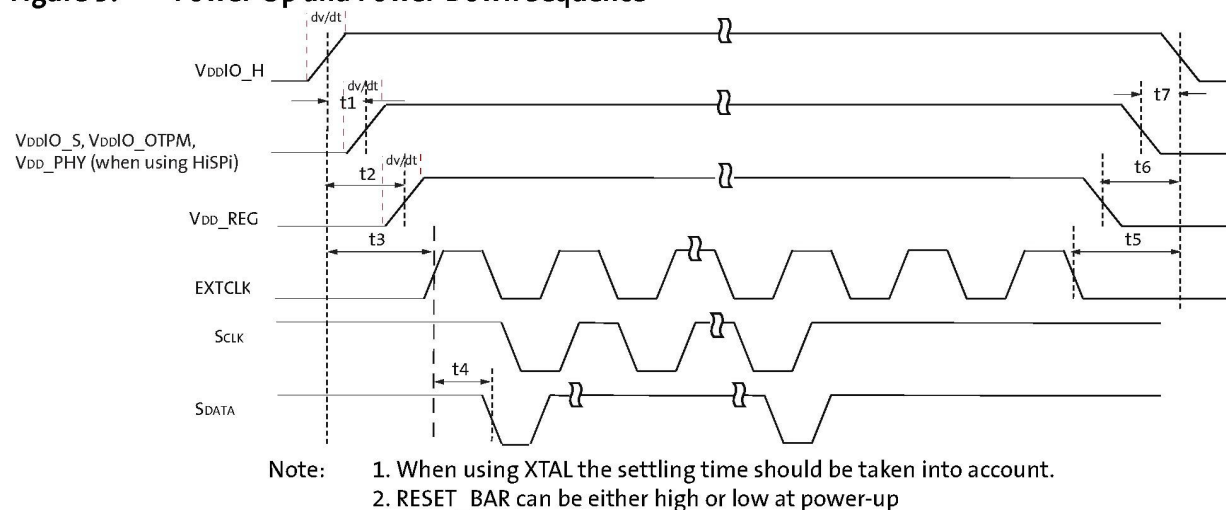

Table 6: Power-Up and Power-Down Signal Timing

| Symbol | Parameter | Min | Typ | Max | Unit |
|--------|---|--------|-----|-----|---------------|
| t1 | Delay from VDDIO_H to VDDIO_S, VDDIO_OTPM, VDD_PHY (when using HiSPi) | 0 | – | 50 | ms |
| t2 | Delay from VDDIO_H to VDD_REG | 0 | – | 50 | ms |
| t3 | EXTCLK activation | t2 + 1 | – | – | ms |
| t4 | First serial command ¹ | 100 | – | – | EXTCLK cycles |
| t5 | EXTCLK cutoff | t6 | – | – | ms |
| t6 | Delay from VDD_REG to VDDIO_H | 0 | – | 50 | ms |
| t7 | Delay from VDDIO_S, VDDIO_OTPM, VDD_PHY (when using HiSPi) to VDDIO_H | 0 | – | 50 | ms |
| dv/dt | Power supply ramp time (slew rate) | – | – | 0.1 | V/ μ s |

Note: 1. When using XTAL the settling time should be taken into account.

Reset

The AP0202AT has three types of reset available:

- A hard reset is issued by toggling the RESET_BAR signal
- A soft reset is issued by writing commands through the two-wire serial interface
- An internal power-on reset

Table 7 on page 15 shows the output states when the part is in various states.

Table 7: Output States

| Name | Hardware States | | Firmware States | | | | Notes |
|------------------------------------|----------------------------|--------------------------|----------------------------|----------------------------|-----------------------------|----------------------------|--|
| | Reset State | Default State | Hard Standby | Soft Standby | Streaming | Idle | |
| EXTCLK | (clock running or stopped) | (clock running) | (clock running or stopped) | (clock running) | (clock running) | (clock running) | Input |
| XTAL | n/a | n/a | n/a | n/a | n/a | n/a | Output |
| RESET_BAR | (asserted) | (negated) | (negated) | (negated) | (negated) | (negated) | Input |
| SCLK | n/a | n/a | (clock running or stopped) | (clock running or stopped) | (clock running or stopped) | (clock running or stopped) | Input. Must always be driven to a valid logic level |
| SDATA | High-impedance | High-impedance | High-impedance | High-impedance | High-impedance | High-impedance | Input/Output. A valid logic level should be established by pull-up |
| SADDR | n/a | n/a | n/a | n/a | n/a | n/a | Input. Must always be driven to a valid logic level |
| FRAME_SYNC | n/a | n/a | n/a | n/a | n/a | n/a | Input. Must always be driven to a valid logic level |
| STANDBY | n/a | (negated) | (asserted) | (negated) | (negated) | (negated) | Input. Must always be driven to a valid logic level |
| EXT_REG | n/a | n/a | n/a | n/a | n/a | n/a | Input. Must always be driven to a valid logic level |
| ENLDO | n/a | n/a | n/a | n/a | n/a | n/a | Input. Must be tied to VDD_REG or GND |
| SPI_SCLK | High-impedance | driven, logic 0 | driven, logic 0 | driven, logic 0 | | | Output |
| SPI_SDI | Internal pull-up enabled | Internal pull-up enabled | Internal pull-up enabled | internal pull-up enabled | | | Input. Internal pull-up permanently enabled. |
| SPI_SDO | High-impedance | driven, logic 0 | driven, logic 0 | driven, logic 0 | | | Output |
| SPI_CS_BAR | High-impedance | driven, logic 1 | driven, logic 1 | driven, logic 1 | | | Output |
| EXT_CLK_OUT | driven, logic 0 | driven, logic 0 | driven, logic 0 | driven, logic 0 | | | Output |
| RESET_BAR_OUT | driven, logic 0 | driven, logic 0 | driven, logic 1 | driven, logic 1 | | | Output. Firmware will release sensor reset |
| M_SCLK | High-impedance | High-impedance | High-impedance | High-impedance | | | Input/Output. A valid logic level should be established by pull-up |
| M_SDATA | High-impedance | High-impedance | High-impedance | High-impedance | | | Input/Output. A valid logic level should be established by pull-up |
| FV_IN, LV_IN, PIXCLK_IN, DIN[11:0] | n/a | n/a | n/a | n/a | Dependent on interface used | n/a | Input. Must always be driven to a valid logic level |

Table 7: Output States (Continued)

| Name | Hardware States | | Firmware States | | | | Notes |
|----------------------------|-----------------|----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|--|
| | Reset State | Default State | Hard Standby | Soft Standby | Streaming | Idle | |
| HiSPiCN | Disabled | Disabled | Dependent on interface used | Dependent on interface used | Dependent on interface used | Dependent on interface used | Input. Will be disabled and can be left floating |
| HiSPiCP | | | | | | | |

| HiSPiOP | | | | | | | |
| HiSPi1N | | | | | | | |
| HiSPi1P | | | | | | | |
| FV_OUT, LV_OUT, PIXCLK_OUT | High-impedance | Varied | Driven if used | Driven if used | Driven if used | Driven if used | Output. Default state dependent on configuration |
| GPIO[6:1] | High-impedance | Input, then high-impedance | Driven if used | Driven if used | Driven if used | Driven if used | Input/Output. |
| TRIGGER_OUT | High-impedance | High-impedance | Driven if used | Driven if used | Driven if used | Driven if used | |
| TEST | n/a | n/a | (negated) | (negated) | (negated) | (negated) | Input. Must always be driven to a valid logic level. |

Hard Reset

The AP0202AT enters the reset state when the external RESET_BAR signal is asserted LOW, as shown in Figure 6. All the output signals will be in a High-Z state.

Figure 6: Hard Reset Operation

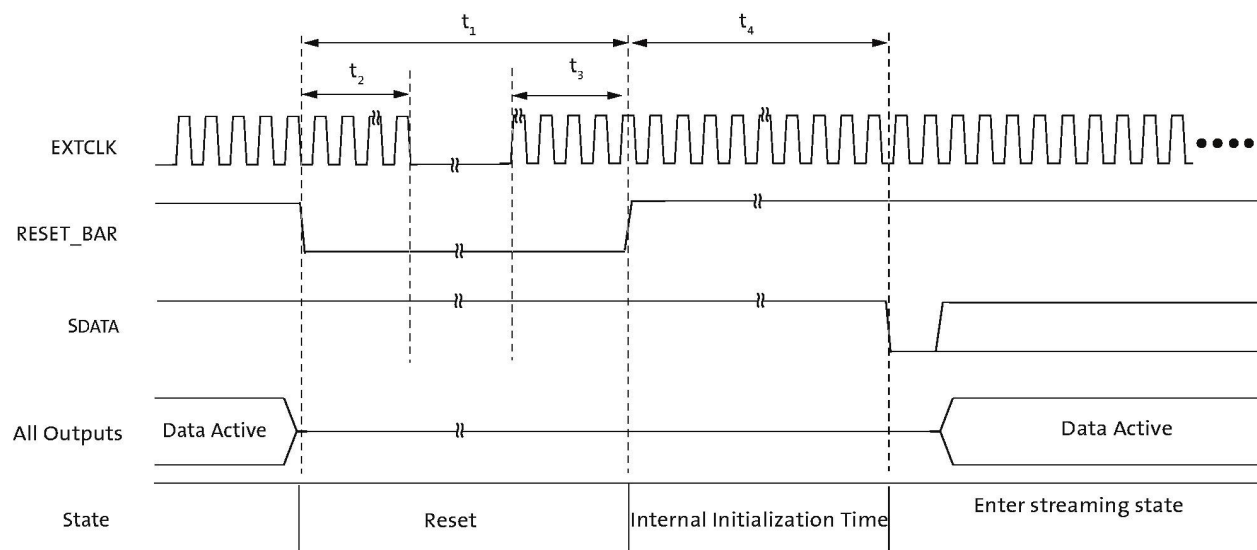

Table 8: Hard Reset

| Symbol | Definition | Min | Typ | Max | Unit |
|--------|---|-----|-----|-----|---------------|
| t_1 | RESET_BAR pulse width | 50 | – | – | EXTCLK cycles |
| t_2 | Active EXTCLK required after RESET_BAR asserted | 10 | – | – | |
| t_3 | Active EXTCLK required before RESET_BAR de-asserted | 10 | – | – | |
| t_4 | First two-wire serial interface communication after RESET is HIGH | 100 | – | – | |

Soft Reset

A soft reset sequence to the AP0202AT can be activated by writing to a register through the two-wire serial interface.

Hard Standby Mode

The AP0202AT can enter hard standby mode by using external STANDBY signal, as shown in Figure 7. In hard standby mode, the total power consumption is reduced. In this mode, the AP0202AT is switched off. A further power reduction can be achieved by turning off the EXTCLK, but this must be restored before de-asserting the STANDBY pin to LOW state to restart the device.

Entering Standby Mode

1. Assert STANDBY signal HIGH.

Exiting Standby Mode

1. De-assert STANDBY signal LOW.

Figure 7: Hard Standby Operation

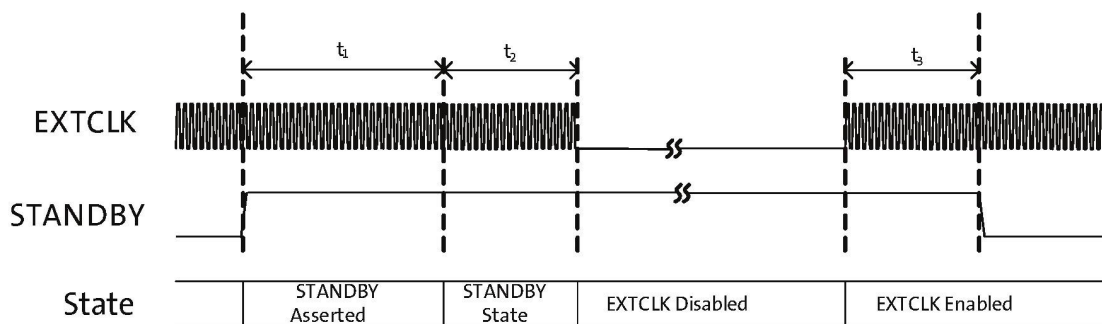

Table 9: Hard Standby Signal Timing

| Symbol | Parameter | Min | Typ | Max | Unit |
|--------|--|-----|-----|-----|---------|
| t_1 | Standby entry complete | – | – | 2 | Frames |
| t_2 | Active EXTCLK required after going into STANDBY mode | 10 | – | – | EXTCLKs |
| t_3 | Active EXTCLK required before STANDBY de-asserted | 10 | – | – | EXTCLKs |

Device Configuration

After power is applied and the device is out of reset (either the power on reset, hard or soft reset), it will enter a boot sequence to configure its operating mode. There are essentially three configuration modes: Flash/EEPROM Config, Auto Config, and Host Config.

The AP0202AT firmware supports a System Configuration phase at start-up. This consists of three sub-phases of execution:

Flash detection, then one of:

- a. Flash Config
- b. Auto Config
- c. Host Config

The System Configuration phase is entered immediately following power-up or reset. Then the firmware performs Flash Detection.

Flash Detection attempts to detect the presence of an SPI Flash or EEPROM device:

- If a device is detected, the firmware switches to the Flash-Config mode.
- If no device is detected, the firmware then samples the SPI_SDI pin state to determine the next mode:
 - If SPI_SDI is low, then it enters the Host-Config mode.
 - If SPI_SDI is high, then it enters the Auto-Config mode.

In the Flash-Config mode, the firmware interrogates the device to determine if it contains valid configuration records:

- If no records are detected, then the firmware enters the Host-Config mode.
- If records are detected, the firmware processes them. By default, when all Flash records are processed the firmware switches to the Host-Config mode. However, the records encoded into the Flash can optionally be used to instruct the firmware to proceed to auto-config, or to start streaming (via a Change-Config).

In the Host-Config mode, the firmware performs no configuration, and remains idle waiting for configuration and commands from the host. The System Configuration phase is effectively complete and the AP0202AT will take no actions until the host issues commands.

Usage Modes

How a camera based on the AP0202AT will be configured depends on what features are used. In the simplest case, an AP0202AT operating in Auto-Config mode with no customized settings might be sufficient.

A back-up camera with dynamic input from the steering system will require a μC with a system bus interface. Flash sizes up to 2 GB are supported. The two-wire bus is adequate since only high-level commands are used.

In the simplest case no EEPROM or Flash memory or μC is required, as shown in Figure 8 on page 20.

Figure 8: Auto-Config Mode (Not supported for AR0230)

The AP0202AT can be configured by a serial EEPROM or Flash through the SPI Interface.

Figure 9: Flash Mode

Figure 10: Host Mode with Flash

In this configuration all settings are communicated to the AP0202AT and sensor through the microcontroller.

Figure 11: Host Mode

Image Flow Processor

Image and color processing in the AP0202AT is implemented as an image flow processor (IFP) coded in hardware logic. During normal operation, the embedded microcontroller will automatically adjust the operating parameters. For normal operation of the AP0202AT, streams of raw image data from the attached image sensor are fed into the color pipeline. The AP0202AT also has the option to select from a number of test patterns to be input instead of sensor data.

Defect Correction

Image stream processing commences with the defect correction function immediately after data decompressing.

To obtain defect free images, the pixels marked defective during sensor readout and the pixels determined defective by the defect correction algorithms are replaced with values derived from the non-defective neighboring pixels.

AdaCD (Adaptive Color Difference)

The next step in the image stream process is noise reduction. The AP0202AT uses a noise reduction filter called AdaCD which focuses on removing color noise while preserving edge details. Automotive applications require good performance in extremely low light, even at high temperature conditions. In these stringent conditions the image sensor is prone to higher noise levels, and so efficient noise reduction techniques are required to circumvent this sensor limitation and deliver a high quality image.

Black Level Subtraction and Digital Gain

After noise reduction, the pixel data goes through black level subtraction and multiplication by a programmable digital gain. Independent color channel digital gain can be adjusted with registers. Black level subtraction (to compensate for sensor data pedestal) is a single value applied to all color channels. If the black level subtraction produces a negative result for a particular pixel, the value of this pixel is set to 0.

Positional Gain Adjustments (PGA)

Lenses tend to produce images whose brightness is significantly attenuated near the edges. There are also other factors causing fixed pattern signal gradients in images captured by image sensors. The cumulative result of all these factors is known as image shading. The AP0202AT has an embedded shading correction module that can be programmed to counter the shading effects on each individual R, Gb, Gr, and B color signal.

The Correction Function

The correction functions can then be applied to each pixel value to equalize the response across the image as follows:

$$P_{corrected}(row, col) = P_{sensor}(row, col) \times f(row, col) \quad (\text{EQ 1})$$

where P are the pixel values and f is the color dependent correction functions for each color channel.

Adaptive Local Tone Mapping (ALTM)

Real world scenes often have very high dynamic range (HDR) that far exceeds the electrical dynamic range of the imager. Dynamic range is defined as the luminance ratio between the brightest and the darkest object in a scene. In recent years many technologies have been developed to capture the full dynamic range of real world scenes. For example, the multiple exposure method is widely adopted for capturing high dynamic range images, which combines a series of low dynamic range images of the same scene taken under different exposure times into a single HDR image.

Even though the new digital imaging technology enables the capture of the full dynamic range, low dynamic range display devices are the limiting factor. Today's typical LCD monitor has contrast ratio around 1,000:1; this contrast ratio is not enough for an HDR image (the contrast ratio for an HDR image is around 250,000:1). Therefore, in order to reproduce HDR images on a low dynamic range display device, the captured high dynamic range must be compressed to the available range of the display device. This is commonly called tone mapping.

Tone mapping methods can be classified into global tone mapping and local tone mapping. Global tone mapping methods apply the same mapping function to all pixels. While global tone mapping methods provide computationally simple and easy to use solutions, they often cause loss of contrast and detail. A local tone mapping is thus necessary in addition to global tone mapping for the reproduction of visually more appealing images that also reveal scene details that are important for automotive safety and surveillance applications. Local tone mapping methods use a spatially variable mapping function determined by the neighborhood of a pixel, which allows it to increase the local contrast and the visibility of some details of the image. Local methods usually yield more pleasing results because they exploit the fact that human vision is more sensitive to local contrast.

ON Semiconductor's ALTM solution significantly improves the performance over global tone mapping. ALTM is directly applied to the Bayer domain to compress the dynamic range from 20-bit to 12-bit. This allows the regular color pipeline to be used for HDR image rendering.

Color Interpolation

In the raw data stream fed by the external sensor to the IFP, each pixel is represented by a 20- or 12-bit integer number, which can be considered proportional to the pixel's response to a one-color light stimulus, red, green, or blue, depending on the pixel's position under the color filter array. Initial data processing steps, up to and including ALTM, preserve the one-color-per-pixel nature of the data stream, but after ALTM it must be converted to a three-colors-per-pixel stream appropriate for standard color processing. The conversion is done by an edge-sensitive color interpolation module. The module pads the incomplete color information available for each pixel with information extracted from an appropriate set of neighboring pixels. The algorithm used to select this set and extract the information seeks the best compromise between preserving edges and filtering out high frequency noise in flat field areas. The edge threshold can be set through register settings.

Color Correction and Aperture Correction

To achieve good color fidelity of the IFP output, interpolated RGB values of all pixels are subjected to color correction. The IFP multiplies each vector of three pixel colors by a 3 x 3 color correction matrix (CCM). The three components of the resulting color vector are

all sums of three 10-bit numbers. The color correction matrix can be either programmed by the user or automatically selected by the auto white balance (AWB) algorithm implemented in the IFP. Color correction should ideally produce output colors that are corrected for the spectral sensitivity and color crosstalk characteristics of the image sensor. The optimal values of the color correction matrix elements depend on those sensor characteristics and on the spectrum of light incident on the sensor. The color correction variables can be adjusted through register settings.

The AP0202AT offers a three-CCM solution that will give the user improved color fidelity when under a wide range of lighting.

To increase image sharpness, a programmable 2D aperture correction (sharpening filter) is applied to color-corrected image data. The gain and threshold for 2D correction can be defined through register settings.

Gamma Correction

The gamma correction curve is implemented as a piecewise linear function with 33 knee points, taking 12-bit arguments and mapping them to 10-bit output. The abscissas of the knee points are fixed at 0, 8, 16, 24, 32, 40, 48, 56, 64, 80, 96, 112, 128, 160, 192, 224, 256, 320, 384, 448, 512, 640, 768, 896, 1024, 1280, 1536, 1792, 2048, 2560, 3072, 3584, and 4096. The 10-bit ordinates are programmable through variables.

The AP0202AT has the ability to calculate the 33-point knee points based on the tuning of `cam_ll_gamma` and `cam_ll_contrast_gradient_bright`. The other method is for the host to program the 33 knee point curve.

Also included in this block is a Fade-to-Black curve which sets all knee points to zero and causes the image to go black in extreme low light conditions.

Color Kill

To remove high- or low-light color artifacts, a color kill circuit is included. It affects only pixels whose luminance exceeds a certain preprogrammed threshold. The U and V values of those pixels are attenuated proportionally to the difference between their luminance and the threshold.

YUV Color Filter

As an optional processing step, noise suppression by one-dimensional low-pass filtering of Y and/or UV signals is possible. A 3- or 5-tap filter can be selected for each signal.

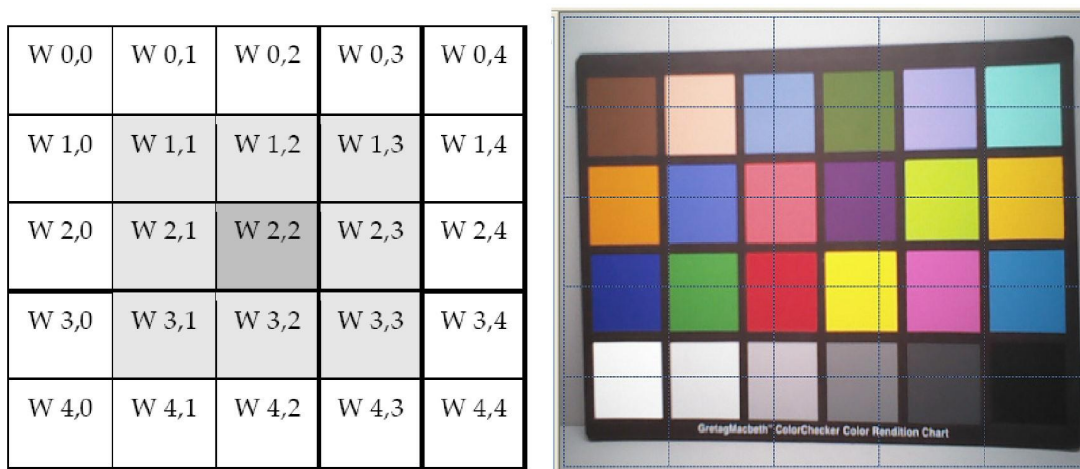

Camera Control and Auto Functions

Auto Exposure

The auto exposure algorithm optimizes scene exposure to minimize clipping and saturation in critical areas of the image. This is achieved by controlling exposure time and analog gains of the external sensor as well as digital gains applied to the image.

Auto exposure is implemented by a firmware algorithm that is running on the embedded microcontroller that analyzes image statistics collected by the exposure measurement engine, makes a decision, and programs the sensor and color pipeline to achieve the desired exposure. The measurement engine subdivides the image into 25 windows organized as a 5 x 5 grid.

Figure 12: 5 x 5 Grid

AE Track

Other algorithm features include the rejection of fast fluctuations in illumination (time averaging), control of speed of response, and control of the sensitivity to small changes. While the default settings are adequate in most situations, the user can program target brightness, measurement window, and other parameters described above.

The AE Track changes AE parameters (integration time, gains, and so on) to drive scene brightness to the programmable target.

To avoid unwanted reaction of AE on small fluctuations of scene brightness or momentary scene changes, the AE track uses a temporal filter for luma and a threshold around the AE luma target. The driver changes AE parameters only if the filtered luma is larger than the AE target step and pushes the luma beyond the threshold.

Auto White Balance

The AP0202AT has a built-in AWB algorithm designed to compensate for the effects of changing spectra of the scene illumination on the quality of the color rendition. The algorithm consists of two major parts: a measurement engine performing statistical analysis of the image and a driver performing the selection of the optimal color correction matrix and IFP digital gain. While default settings of these algorithms are adequate

in most situations, the user can reprogram base color correction matrices, place limits on color channel gains, and control the speed of both matrix and gain adjustments. The AP0202AT AWB displays the current AWB position in color temperature, the range of which will be defined when programming the CCM matrices.

The region of interest can be controlled through the combination of an inclusion window and an exclusion window.

Dual Band IRCF

For some applications a day/night filter would be switched in/out, this option is an additional cost to the camera system. The AP0202AT supports the use of dual band IRCF, which removes the need for the switching day/night filter. Tuning support is provided for this usage case. Refer to the AP0202AT developer guide for details.

Exposure and White Balance Modes

The AP0202AT supports auto and manual exposure and white balance modes. In addition, it will operate within synchronized multi-camera systems. In this use case, one camera within the system will be the 'master', and the others 'slaves'. The master is used to calculate the appropriate exposure and white balance. This is then applied to all slaves concurrently under host control.

Auto Mode

In Auto Exposure mode the AE algorithm is responsible for calculating the appropriate exposure to keep the desired scene brightness, and for applying the exposure to the underlying hardware. In Auto White Balance mode the AWB algorithm is responsible for calculating the color temperature of the scene and applying the appropriate red and blue gains to compensate.

Triggered Auto Mode

The Triggered Auto Exposure and Triggered Auto White Balance modes are intended for the multi-camera use cases, where a host is controlling the exposure and white balance of a number of cameras. The idea is that one camera is in triggered-auto mode (the master), and the others in host-controlled mode (slaves). The master camera must calculate the exposure and gains, the host then copies this to the slaves, and all changes are then applied at the same time.

Manual Mode

Manual mode is intended to allow simple manual exposure and white balance control by the host. The host needs to set the CAM_AET_EXPOSURE_TIME_MS, CAM_AET_EXPOSURE_GAIN and CAM_AWB_COLOR_TEMPERATURE controls and trigger an exposure, the camera will calculate the appropriate integration times and gains.

Host Controlled

The Host Controlled mode is intended to give the host full control over exposure and gains

Flicker Avoidance

Flicker is caused by artificial light which is usually generated from incandescent or fluorescent light sources. The frequency of alternating current (AC) power sources in most countries is 50 Hz or 60 Hz, which emit light with alternating inverted positive and nega-

tive voltages. This results in a light source reflecting from an object to have a light intensity change frequency of 100 Hz and 120 Hz respectively. If the integration time is not an integer multiple of the period of AC powered light intensity, flicker can be visible. The AP0202AT can be programmed to avoid flicker for 50 or 60 Hertz. For integration times below the light intensity period (10ms for 50Hz environment, 8.33 ms in 60 Hz environments), flicker cannot be avoided. The AP0202AT supports an indoor AE mode, that will ensure flicker-free operation.

Flicker Detection

The AP0202AT supports flicker detection, the algorithm is designed only to detect a 50Hz or 60Hz flicker source.

Output Formatting

The pixel output data in AP0202AT will be transmitted as an 8- to 24-bit word over one or two clocks.

Uncompressed YCbCr Data Ordering

The AP0202AT supports swapping YCbCr mode, as illustrated in Table 10.

Table 10: YCbCr Output Data Ordering

| Mode | Data Sequence | | | |
|-------------------|---------------|-----|------|------|
| Default (no swap) | Cbi | Yi | Cri | Yi+1 |
| Swapped CrCb | Cri | Yi | Cbi | Yi+1 |
| Swapped YC | Yi | Cbi | Yi+1 | Cri |
| Swapped CrCb, YC | Yi | Cri | Yi+1 | Cbi |

The data ordering for the YCbCr output modes for AP0202AT are shown in Table 11 and Table 12:

Table 11: YCbCr Output Modes (Default mode; cam_port_parallel_msb_align=0x1)

| Mode | Byte | Pixel i | Pixel i+1 | Notes |
|-----------------|----------------------|---------|-----------|--|
| YCbCr_422_8_8 | Odd (DOUT [23:16]) | Cbi | Cri | Data range of 0-255 (Y=16-235 and C=16-240) |
| | Even (DOUT [23:16]) | Yi | Yi+1 | |
| YCbCr_422_10_10 | Odd (DOUT [23:14]) | Cbi | Cri | Data range of 0-1023 (Y=64-940 and C=64-960) |
| | Even (DOUT [23:14]) | Yi | Yi+1 | |
| YCbCr_422_16 | Single (DOUT [23:8]) | Cbi_Yi | Cri_Yi+1 | Data range of 0-255 (Y=16-235 and C=16-240) |
| YCbCr_422_20 | Single (DOUT [23:4]) | Cbi_Yi | Cri_Yi+1 | Data range of 0-1023 (Y=64-940 and C=64-960) |

Note: Odd means first cycle; even means second cycle.

Table 12: YCbCr Output Modes (Default mode; cam_port_parallel_msb_align=0x0)

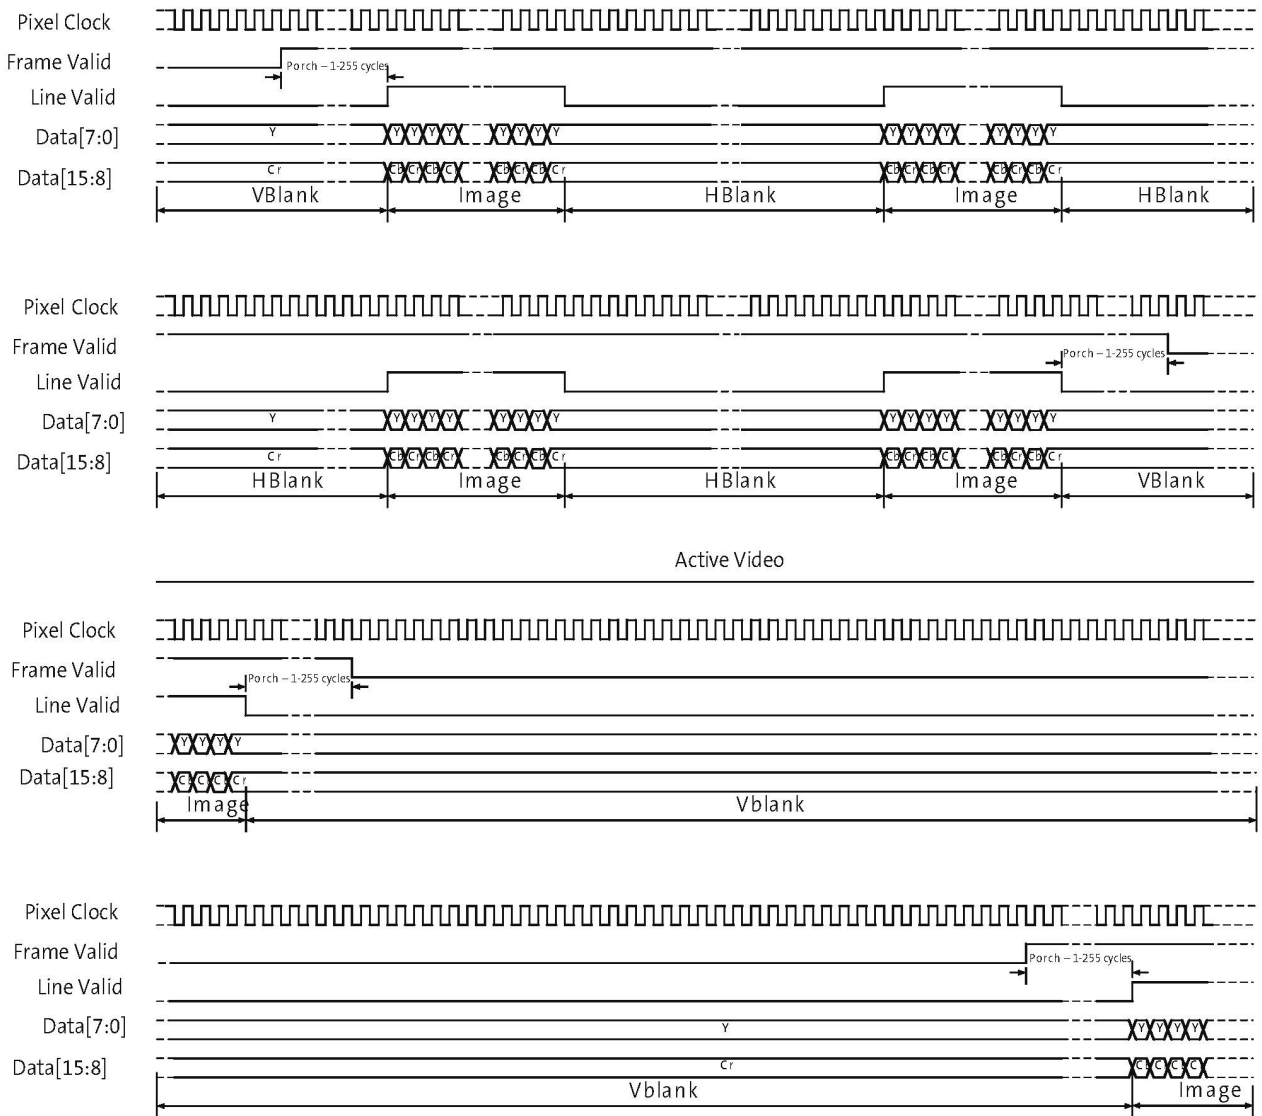

| Mode | Byte | Pixel i | Pixel i+1 | Notes |

Crossbar

The AP0202AT Rev 2 has a cross-bar functionality that allows the assignment of any Data, Vsync, Hsync, line valid, and frame valid signal to any of the 27 possible parallel output pins. Normally, as is the case for the legacy mode of the AP0202AT REV1, the 27 output pins are named DOUT[23:0], LINE_VALID, FRAM_VALID and META_LINE_VALID.

For AP0202 REV2 these output pins can be considered as DOUT[26:0] with no special assignments as any data bit or control signal may be assigned to any output. If desired, each data bit or control signal may even be assigned to multiple outputs at once.

The crossbar has 27 registers that define how each input should be assigned to each of the 27 possible outputs.

This feature affords a large amount of flexibility for the customer. For example, during PCB layout, the pins can be adjusted to minimize crossovers and optimize routing paths.

Embedded Data and Statistics

Some ON Semiconductor sensor's support a feature that, if enabled, inserts two extra lines at the beginning and end of each frame which contain information about that frame. The first two lines contain specific register values that were used to capture that frame. These values allow the host to know certain important things about how the sensor was configured for that frame, e.g. exposure, gain, image size, etc. The last two lines contain statistics about the image that was captured, e.g. mean values, intensity histograms, etc.

The AP0202AT includes these embedded data in its image data output as embedded data lines in all modes. This feature is supported on output image sizes from full resolution to VGA.

Slave Two-Wire Serial Interface (CCIS)

The two-wire slave serial interface bus enables read/write access to control and status registers within the AP0202AT.

The interface protocol uses a master/slave model in which a master controls one or more slave devices.

Protocol

Data transfers on the two-wire serial interface bus are performed by a sequence of low-level protocol elements, as follows:

- a start or restart condition
- a slave address/data direction byte
- a 16-bit register address
- an acknowledge or a no-acknowledge bit
- data bytes
- a stop condition

The bus is idle when both SCLK and SDATA are HIGH. Control of the bus is initiated with a start condition, and the bus is released with a stop condition. Only the master can generate the start and stop conditions.

The SADDR pin is used to select between two different addresses in case of conflict with another device. If SADDR is LOW, the slave address is 0x90; if SADDR is HIGH, the slave address is 0xBA. See Table 22 below. The user can change the slave address by changing a register value.

Table 22: Two-Wire Interface ID Address Switching

| SADDR | Two-Wire Interface Address ID |
|-------|-------------------------------|
| 0 | 0x90 |
| 1 | 0xBA |

Start Condition

A start condition is defined as a HIGH-to-LOW transition on SDATA while SCLK is HIGH.

At the end of a transfer, the master can generate a start condition without previously generating a stop condition; this is known as a “repeated start” or “restart” condition.

Data Transfer

Data is transferred serially, 8 bits at a time, with the MSB transmitted first. Each byte of data is followed by an acknowledge bit or a no-acknowledge bit. This data transfer mechanism is used for the slave address/data direction byte and for message bytes. One data bit is transferred during each SCLK clock period. SDATA can change when SCLK is low and must be stable while SCLK is HIGH.

Slave Address/Data Direction Byte

Bits [7:1] of this byte represent the device slave address and bit [0] indicates the data transfer direction. A “0” in bit [0] indicates a write, and a “1” indicates a read. The default slave addresses used by the AP0202AT are 0x90 (write address) and 0x91 (read address). Alternate slave addresses of 0xBA (write address) and 0xBB (read address) can be selected by asserting the SADDR input signal.

Message Byte

Message bytes are used for sending register addresses and register write data to the slave device and for retrieving register read data. The protocol used is outside the scope of the two-wire serial interface specification.

Acknowledge Bit

Each 8-bit data transfer is followed by an acknowledge bit or a no-acknowledge bit in the SCLK clock period following the data transfer. The transmitter (which is the master when writing, or the slave when reading) releases SDATA. The receiver indicates an acknowledge bit by driving SDATA LOW. As for data transfers, SDATA can change when SCLK is LOW and must be stable while SCLK is HIGH.

No-Acknowledge Bit

The no-acknowledge bit is generated when the receiver does not drive SDATA low during the SCLK clock period following a data transfer. A no-acknowledge bit is used to terminate a read sequence.

Stop Condition

A stop condition is defined as a LOW-to-HIGH transition on SDATA while SCLK is HIGH.

Typical Operation

A typical READ or WRITE sequence begins by the master generating a start condition on the bus. After the start condition, the master sends the 8-bit slave address/data direction byte. The last bit indicates whether the request is for a READ or a WRITE, where a “0” indicates a WRITE and a “1” indicates a READ. If the address matches the address of the slave device, the slave device acknowledges receipt of the address by generating an acknowledge bit on the bus.

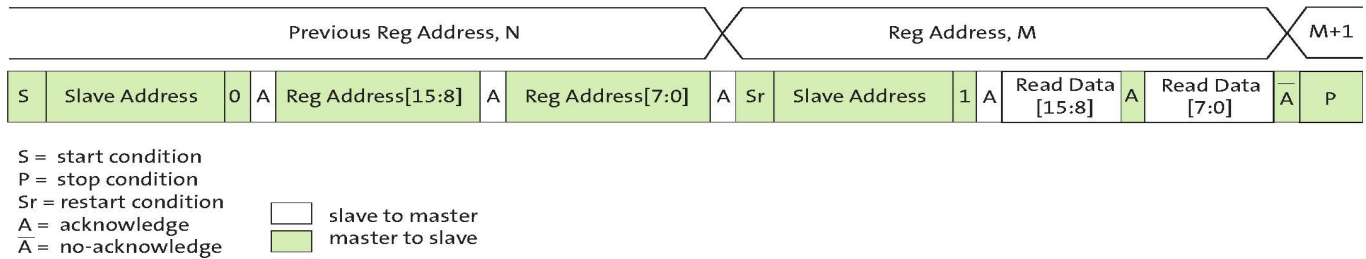

If the request was a WRITE, the master then transfers the 16-bit register address to which a WRITE will take place. This transfer takes place as two 8-bit sequences and the slave sends an acknowledge bit after each sequence to indicate that the byte has been received. The master will then transfer the 16-bit data, as two 8-bit sequences and the slave sends an acknowledge bit after each sequence to indicate that the byte has been received. The master stops writing by generating a (re)start or stop condition. If the request was a READ, the master sends the 8-bit write slave address/data direction byte and 16-bit register address, just as in the write request. The master then generates a (re)start condition and the 8-bit read slave address/data direction byte, and clocks out the register data, 8 bits at a time. The master generates an acknowledge bit after each 8-bit transfer. The data transfer is stopped when the master sends a no-acknowledge bit.

Single READ from Random Location

Figure 22 shows the typical READ cycle of the host to the AP0202AT. The first two bytes sent by the host are an internal 16-bit register address. The following 2-byte READ cycle sends the contents of the registers to host.

Figure 22: Single READ from Random Location

Single READ from Current Location

Figure 23 shows the single READ cycle without writing the address. The internal address will use the previous address value written to the register.

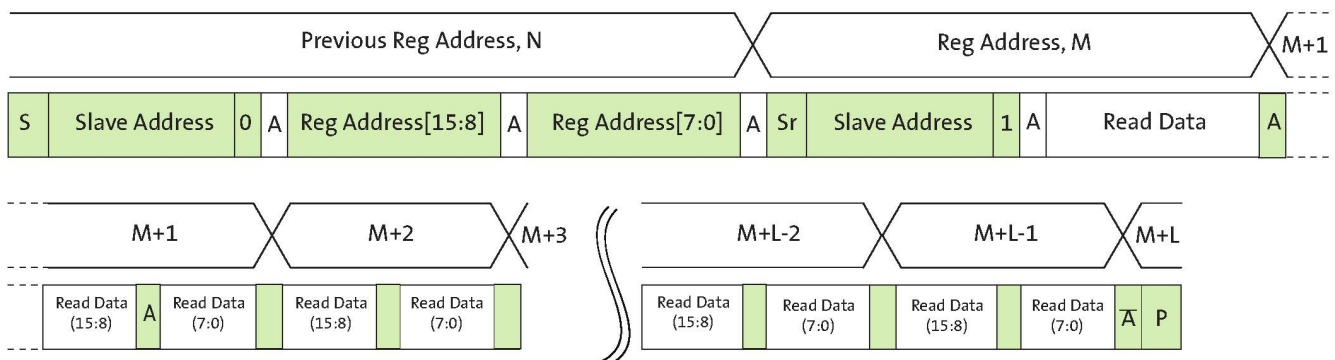

Figure 23: Single Read from Current Location

Sequential READ, Start from Random Location

This sequence (Figure 24) starts in the same way as the single READ from random location (Figure 22 on page 41). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte READs until “L” bytes have been read.

Figure 24: Sequential READ, Start from Random Location

Sequential READ, Start from Current Location

This sequence (Figure 25) starts in the same way as the single READ from current location (Figure 23). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte reads until “L” bytes have been read.

Figure 25: Sequential READ, Start from Current Location

Single Write to Random Location

Figure 26 shows the typical WRITE cycle from the host to the AP0202AT. The first 2 bytes indicate a 16-bit address of the internal registers with most-significant byte first. The following 2 bytes indicate the 16-bit data.

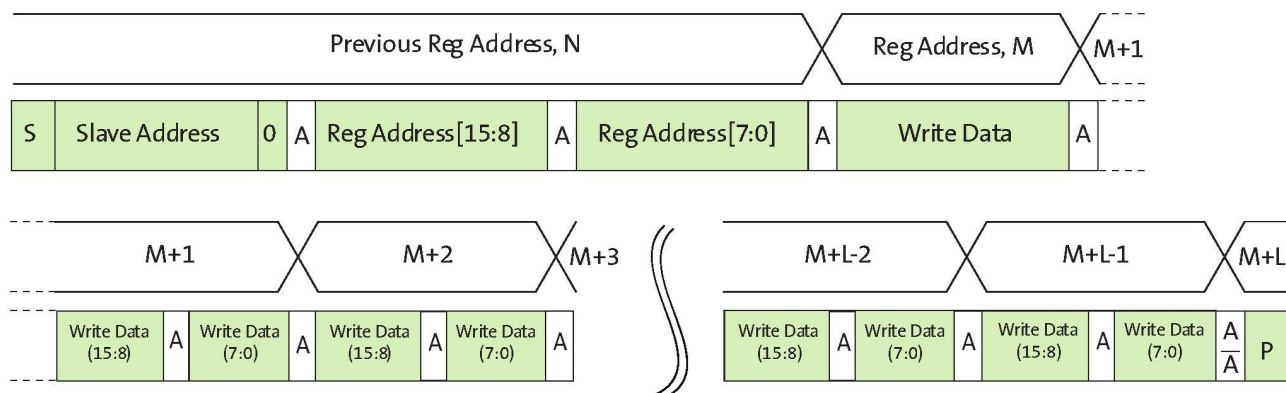

Figure 26: Single WRITE to Random Location

Sequential WRITE, Start at Random Location

This sequence (Figure 27) starts in the same way as the single WRITE to random location (Figure 26). Instead of generating a no-acknowledge bit after the first byte of data has been transferred, the master generates an acknowledge bit and continues to perform byte writes until “L” bytes have been written. The WRITE is terminated by the master generating a stop condition.

Figure 27: Sequential WRITE, Start at Random Location

Supported SPI Devices

The supported devices are those that conform to the JEDEC-compliant programming interface. Please contact ON Semiconductor for specific design criteria and requirements. The maximum supported device size is 2 Gb.

Host Command Interface

The AP0202AT has a mechanism to write higher level commands, the Host Command Interface (HCI). Once a command has been written through the HCI, it will be executed by on chip firmware and the results are reported back. EEPROM or Flash memory is also available to store commands for later execution.

Full details of the Host Command Interface can be found in the AP0202AT Host Command Interface (HCI) Specification document.

Specifications

Caution Stresses greater than those listed in Table 23 may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 23: Absolute Maximum Ratings

| Parameter | Rating | | Unit |
|-----------------------------------|--------|--------------------------|------|
| | Min | Max | |
| Digital power (1.8V) | -0.3 | 4.95 | V |
| Host I/O power (1.8V, 2.8V, 3.3V) | 1.7 | 4.95 | V |
| Sensor I/O power (1.8V, 2.8V) | 1.7 | 4.95 | V |
| PLL power | 1.1 | 1.8 | V |
| Digital core power | 1.1 | 1.8 | V |
| OTPM power (2.8V, 3.3V) | 2.25 | 4.95 | V |
| DC Input Voltage | -0.3 | V _{DDIO_*} +0.3 | V |
| DC Output Voltage | -0.3 | V _{DDIO_*} +0.3 | V |
| Storage temperature | -50 | 150 | °C |

Table 24: Electrical Characteristics and Operating Conditions

| Parameter | Condition | Min | Typ | Max | Unit |
|--|-----------|------|-------------|------|------|
| Supply input to on-chip regulator (V _{DD_REG}) | | 1.71 | 1.8 | 1.89 | V |
| Host IO voltage (V _{DDIO_H}) | | 1.71 | 1.8/2.8/3.3 | 3.46 | V |
| Sensor IO voltage (V _{DDIO_S}) | | 1.71 | 1.8/2.8 | 2.94 | V |
| Core voltage (V _{DD}) | | 1.14 | 1.2 | 1.26 | V |
| PLL voltage (V _{DD_PLL}) | | 1.14 | 1.2 | 1.26 | V |
| HiSPi PHY voltage (V _{DD_PHY}) | | 2.3 | 2.8 | 3.1 | V |
| OTPM power supply (V _{DDIO_OTPM}) | | 2.38 | 2.8/3.3 | 3.47 | V |
| Functional operating temperature (ambient - T _A) | | -40 | | 105 | °C |

Figure 28: I/O Timing Diagram

 Table 25: I/O Timing Characteristics - Parallel Mode (2.8V VDD_IO)^{1,2}

| Symbol | Definition | Condition | Min | Typ | Max | Unit |
|---------------|--------------------------|-----------------|------|-------|-----|------|
| $f_{EXTCLK1}$ | Input clock frequency | PLL Enabled | 6 | - | 30 | MHz |
| t_R | Input clock rise time | 10%-90% VDDIO_H | - | 2 | 5 | ns |
| t_F | Input clock fall time | 10%-90% VDDIO_H | - | 2 | 5 | ns |
| t_{JITTER} | Input clock jitter | | - | 500 | - | ps |
| t_{RP} | PIXCLK_OUT rise time | | - | | - | ns |
| t_{FP} | PIXCLK_OUT fall time | | - | | - | ns |
| | Duty Cycle | | 40 | 50 | 60 | % |
| f_{PIXCLK} | PIXCLK_OUT frequency | | 18 | 74.25 | 125 | MHz |
| t_{PD} | PIXCLK_OUT to data valid | | -3.5 | - | 2.0 | ns |
| t_{PFH} | PIXCLK_OUT to FV HIGH | | -3.5 | - | 2.0 | ns |
| t_{PLH} | PIXCLK_OUT to LV HIGH | | -3.5 | - | 2.0 | ns |
| t_{PFL} | PIXCLK_OUT to FV LOW | | -3.5 | - | 2.0 | ns |
| t_{PLL} | PIXCLK_OUT to LV LOW | | -3.5 | - | 2.0 | ns |

- Notes:
1. Minimum and maximum values are taken at 105°C, 2.5V and -40°C, 3.1V. All values are taken at the 50% transition point. The loading used is 10 pF.
 2. Jitter from PIXCLK is already taken into account in the data for all of the output parameters.
 3. Max PIXCLK frequency varies with IO voltage.

Table 26: I/O Timing Characteristics - Parallel Mode (1.8V VDD_IO)^{1,2}

| Symbol | Definition | Condition | Min | Typ | Max | Unit |
|----------------------|--------------------------|-----------------|------|-------|-----|------|
| f _{EXTCLK1} | Input clock frequency | PLL Enabled | 6 | - | 30 | MHz |
| t _R | Input clock rise time | 10%-90% VDDIO_H | - | 2 | 5 | ns |
| t _F | Input clock fall time | 10%-90% VDDIO_H | - | 2 | 5 | ns |
| t _{JITTER} | Input clock jitter | | - | 500 | - | ps |
| t _{RP} | PIXCLK_OUT rise time | | - | | - | ns |
| t _{FP} | PIXCLK_OUT fall time | | - | | - | ns |
| | Duty Cycle | | 40 | 50 | 60 | % |
| f _{PIXCLK} | PIXCLK_OUT frequency | | 18 | 74.25 | 80 | ns |
| t _{PD} | PIXCLK_OUT to data valid | | -3.5 | - | 2.0 | ns |
| t _{PFH} | PIXCLK_OUT to FV HIGH | | -3.5 | - | 2.0 | ns |
| t _{PLH} | PIXCLK_OUT to LV HIGH | | -3.5 | - | 2.0 | ns |
| t _{PFL} | PIXCLK_OUT to FV LOW | | -3.5 | - | 2.0 | ns |
| t _{PLL} | PIXCLK_OUT to LV LOW | | -3.5 | - | 2.0 | ns |

- Notes: 1. Minimum and maximum values are taken at 105, 1.7V and -40C, 1.95V. All values are taken at the 50% transition point. The loading used is 10 pF.
 2. Jitter from PIXCLK_OUT is already taken into account in the data for all of the output parameters.

Table 27: DC Electrical Characteristics

| Symbol | Parameter | Condition | Min | Max | Unit | Notes |
|-----------------|-----------------------|---|-----------------------------|----------------------------|------|-------|
| V _{IH} | Input HIGH voltage | | VDDIO_H or VDDIO_S* 0.8 | - | V | 1 |
| V _{IL} | Input LOW voltage | | - | VDDIO_H or VDDIO_S* 0.2 | V | 1 |
| I _{IN} | Input leakage current | V _{IN} = 0V or V _{IN} = VDDIO_H or VDDIO_S | | 10 | μA | 2 |
| V _{OH} | Output HIGH voltage | | VDDIO_H or VDDIO_S* 0.80 | - | V | |
| V _{OL} | Output LOW voltage | | - | VDDIO_H or VDDIO_S* 0.2 | V | |

- Notes: 1. V_{IL} and V_{IH} have min/max limitations specified by absolute ratings.
 2. Excludes pins that have internal PU resistors.

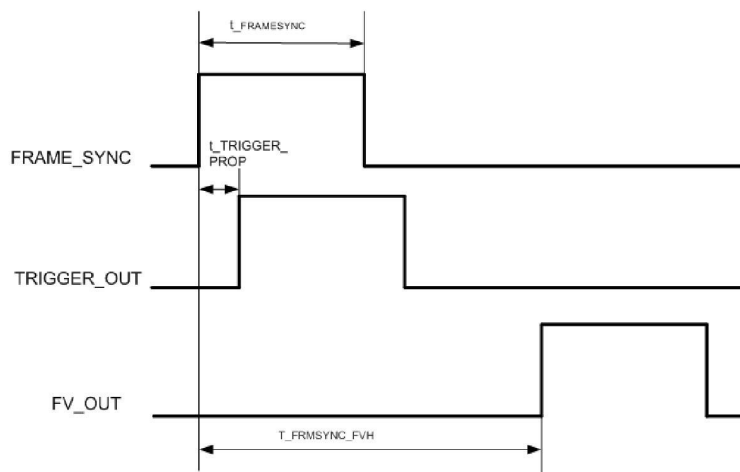

Table 28: Input Clocks

| Clock | Min (MHz) | Typical (MHz) | Max (MHz) | Description |
|-----------|-----------------------|---------------|-----------|---|
| EXTCLK | 10 - osc 20 - xtal | 27 | 29 | Primary system clock. Drives PLLs. Crystal frequency range is 20-29 MHz, otherwise 10-29 MHz. |
| PIXCLK_IN | 10 | 74.25 | 80 | Clock for parallel input bus (from sensor). |
| HiSPi_CLK | 30 | | 300 | Clock for HISPI image data receiver. |

Table 29: Output Clocks

| Clock | Min (MHz) | Typical (MHz) | Max (MHz) | Description |
|------------|-----------|---------------|-----------|--|
| EXTCLK_OUT | 10 | 27 | 29 | Primary clock to sensor. Equals EXTCLK. |
| PIXCLK_OUT | 18 | 74.25 | 80 | Clock of parallel output bus. If pad voltage is 1.8 V nominal, then max frequency is 80 MHz. If pad voltage is 2.5 V, the hold time will decrease to 1.9 ns from 2.0 ns at 125 MHz. If pad voltage is 3.3 V, then the max frequency is 125 MHz. |
| SPI_CLK | 1 | | 20 | SPI clock to nonvolatile external memory. |

Figure 29: Frame_Sync Diagram

Table 30: Trigger Timing

| Parameter | Name | Conditions | Min | Typ | Max | Unit |
|---------------------------|---------------------|------------|---------------------------------------|-----|-----|---------------|
| FRAME_SYNC to FV_OUT | $t_{FRMSYNC_FVH}$ | | 8 lines+ exposure time + sensor delay | – | – | Lines |
| FRAME_SYNC to TRIGGER_OUT | $t_{TRIGGER_PROP}$ | | – | – | 30 | ns |
| t_{FRAME_SYNC} | $t_{FRAMESYNC}$ | | 3 | – | – | EXTCLK cycles |

Table 31: Standby Current Consumption

Default Setup Conditions: $f_{EXTCLK} = 27$ MHz, $V_{DD_REG} = 1.8$ V; V_{DDIO_H} not included in measurement
 $V_{DDIO_S} = 1.8$ V, $V_{DDIO_OTPM} = 2.8$ V, $V_{DD_PHY} = 2.8$ V, $T_A = 105^\circ\text{C}$ unless otherwise stated

| Parameter | Condition | Typ | Max | Unit |
|---------------------|-----------|------|------|------|
| IDD_REG | | 1.50 | 1.91 | mA |
| IDDIO_S | | 0.19 | 0.24 | mA |
| IDDIO_H | | 1.20 | 1.52 | mA |
| IDDIO_OTPM | | 0.18 | 0.23 | mA |
| IDDIO_PHY | | 0.00 | 0.00 | mA |
| Total Standby Power | | 7.46 | 9.47 | mW |

Table 32: Inrush Current

| Supply | Voltage | Typ | Max | Unit |
|------------------|---------|-----|-----|------|
| V_{DD_REG} | 1.8 | 130 | 180 | mA |
| V_{DDIO_H} | 2.8/3.3 | 140 | 190 | mA |
| V_{DDIO_S} | 2.8 | 90 | 105 | mA |
| V_{DD_PHY} | 2.8 | 180 | 180 | mA |
| V_{DDIO_OTPM} | 2.8/3.3 | 140 | 160 | mA |

Table 33: Operating Current Consumption

Default Setup Conditions: $f_{EXTCLK} = 27 \text{ MHz}$, $V_{DD_REG} = 1.8\text{V}$; V_{DDIO_H} not included in measurement
 $V_{DDIO_S} = 1.8\text{V}$, $V_{DDIO_OTPM} = 2.5\text{V}$, $V_{DD_PHY} = 2.5\text{V}$, $T_A = 105^\circ\text{C}$ unless otherwise stated

| Symbol | Input Data from Sensor | Min | Typ | Max | Unit |
|-------------------------|------------------------|-----|-----|-----|------|
| V_{DD_REG} | YCbCr | | 85 | 108 | mA |
| V_{DDIO_S} | YCbCr | | 3.0 | 4.0 | mA |
| V_{DDIO_OTPM} | YCbCr | | 0.2 | 0.3 | mA |
| V_{DD_PHY} | YCbCr | | 0.2 | 0.3 | mA |
| Total Power Consumption | YCbCr | | 159 | 202 | mW |

Two-Wire Serial Register Interface

The electrical characteristics of the two-wire serial register interface (SCLK, SDATA) are shown in Figure 30 and Table 34.

Figure 30: Slave Two Wire Serial Bus Timing Parameters (CCIS)

Table 34: Slave Two-Wire Serial Bus Characteristics (CCIS)

Default Setup Conditions: $f_{EXTCLK} = 27 \text{ MHz}$; $V_{DDIO_H} = V_{DD_OTPM} = 2.8\text{V}$; $V_{DD_REG} = V_{DDIO_S} = 1.8\text{V}$; $T_A = 25^\circ\text{C}$ unless otherwise stated

| Parameter | Symbol | Standard-Mode | | Fast-Mode | | Unit |
|--|----------------|----------------|-------------------|----------------|------------------|------------------|
| | | Min | Max | Min | Max | |
| SCLK Clock Frequency | f_{SCL} | 0 | 100 | 0 | 400 | KHz |
| Hold time (repeated) START condition. After this period, the first clock pulse is generated | $t_{HD;STA}$ | 4.0 | - | 0.6 | - | μs |
| LOW period of the SCLK clock | t_{LOW} | 4.7 | - | 1.3 | - | μs |
| HIGH period of the SCLK clock | t_{HIGH} | 4.0 | - | 0.6 | - | μs |
| Set-up time for a repeated START condition | $t_{SU;STA}$ | 4.7 | - | 0.6 | - | μs |
| Data hold time | $t_{HD;DAT}$ | 0 ² | 3.45 ³ | 0 | 0.9 ³ | μs |
| Data set-up time | $t_{SU;DAT}$ | 250 | - | 100 | - | ns |
| Rise time of both SDATA and SCLK signals (10-90%) | t_r | - | 1000 | $20 + 0.1Cb^4$ | 300 | ns |
| Fall time of both SDATA and SCLK signals (10-90%) | t_f | - | 300 | $20 + 0.1Cb^4$ | 300 | ns |
| Set-up time for STOP condition | $t_{SU;STO}$ | 4.0 | - | 0.6 | - | μs |
| Bus free time between a STOP and START condition | t_{BUF} | 4.7 | - | 1.3 | - | μs |
| Capacitive load for each bus line | C_b | - | 400 | - | 400 | pF |
| Serial interface input pin capacitance | C_{IN_SI} | - | 3.3 | - | 3.3 | pF |
| SDATA max load capacitance | C_{LOAD_SD} | - | 30 | - | 30 | pF |
| SDATA pull-up resistor | R_{SD} | 1.5 | 4.7 | 1.5 | 4.7 | $\text{K}\Omega$ |

- Notes:
1. All values referred to $V_{IHmin} = 0.9 V_{DDIO_H}$ and $V_{ILmax} = 0.1 V_{DDIO_H}$ levels. $EXCLK = 27 \text{ MHz}$.
 2. A device must internally provide a hold time of at least 300 ns for the SDATA signal to bridge the undefined region of the falling edge of SCLK.
 3. The maximum $t_{HD;DAT}$ has only to be met if the device does not stretch the LOW period (t_{LOW}) of the SCLK signal.
 4. C_b = total capacitance of one bus line in pF.

The electrical characteristics of the master two-wire serial register interface (M_SCLK, M_SDATA) are shown in Figure 31 and Table 35.

Figure 31: Master Two Wire Serial Bus Timing Parameters (CCIM)

Table 35: Master Two-Wire Serial Bus Characteristics (CCIM)

Default Setup Conditions: $f_{EXTCLK} = 27 \text{ MHz}$; $V_{DDIO_H} = V_{DD_OTPM} = 2.8\text{V}$; $V_{DD_REG} = V_{DDIO_S} = 1.8\text{V}$; $T_A = 25^\circ\text{C}$ unless otherwise stated

| Parameter | Symbol | Standard-Mode | | Fast-Mode | | Unit |
|--|----------------|----------------|-------------------|----------------|------------------|---------------|
| | | Min | Max | Min | Max | |
| M_SCLK Clock Frequency | f_{SCL} | 0 | 100 | 0 | 400 | KHz |
| Hold time (repeated) START condition. After this period, the first clock pulse is generated | $t_{HD;STA}$ | 4.0 | - | 0.6 | - | μs |
| LOW period of the M_SCLK clock | t_{LOW} | 4.7 | - | 1.2 | - | μs |
| HIGH period of the M_SCLK clock | t_{HIGH} | 4.0 | - | 0.6 | - | μs |
| Set-up time for a repeated START condition | $t_{SU;STA}$ | 4.7 | - | 0.6 | - | μs |
| Data hold time | $t_{HD;DAT}$ | 0 ² | 3.45 ³ | 0 | 0.9 ³ | μs |
| Data set-up time | $t_{SU;DAT}$ | 250 | - | 100 | - | ns |
| Rise time of both M_SDATA and M_SCLK time (10-90%) | t_r | - | 1000 | $20 + 0.1Cb^4$ | 300 | ns |
| Fall time of both M_SDATA and M_SCLK time (10-90%) | t_f | - | 300 | $20 + 0.1Cb^4$ | 300 | ns |
| Set-up time for STOP condition | $t_{SU;STO}$ | 4.0 | - | 0.6 | - | μs |
| Bus free time between a STOP and START condition | t_{BUf} | 4.7 | - | 1.3 | - | μs |
| Capacitive load for each bus line | C_b | - | 400 | - | 400 | pF |
| Serial interface input pin capacitance | C_{IN_SI} | - | 3.3 | - | 3.3 | pF |
| M_SDATA max load capacitance | C_{LOAD_SD} | - | 30 | - | 30 | pF |
| M_SDATA pull-up resistor | R_{SD} | 1.5 | 4.7 | 1.5 | 4.7 | $K\Omega$ |

- Notes:
1. All values referred to $V_{IHmin} = 0.9 V_{DDIO}$ and $V_{ILmax} = 0.1 V_{DDIO}$ levels. $EXCLK = 27 \text{ MHz}$.
 2. A device must internally provide a hold time of at least 300 ns for the M_SDATA signal to bridge the undefined region of the falling edge of M_SCLK.
 3. The maximum $t_{HD;DAT}$ has only to be met if the device does not stretch the LOW period (t_{LOW}) of the M_SCLK signal.
 4. C_b = total capacitance of one bus line in pF.
